Technological advancements have greatly impacted labor market dynamics, leaving a psychological impact on workers. Although some studies have explored such labor market changes and their effects on workers, they are limited to self-reported data, such as surveys and questionnaires. In this article, we propose a new approach for identifying information workers' challenges and their impact on workers' emotional well-being using large-scale, inexpensive, and near-real-time online social network data. While the research is situated within the broader Future of Work context shaped by technological change, the data collected and analyzed focus specifically on IT-related skills and topics discussed on Reddit, rather than on artificial intelligence itself. Analyzing over 700,000 Reddit posts related to IT occupations, we identify major labor market topics, including education and skill development, job search, and employment concerns, and examine how workers' emotional expressions vary across gender and age groups. Our findings reveal systematic differences in how workers from different demographic groups disclose their needs and emotional states online. This work demonstrates the value of social media data as a complementary lens for understanding workers' challenges in the knowledge economy. It highlights the potential of online communities as vehicles for peer support and well-being interventions.

1 Introduction

Online social networks play a significant role in many aspects of people's lives, and their careers are no exception. People increasingly engage with social media for various career-related reasons, from skill development to job search [39, 70, 80, 86, 89, 105, 106, 108]. Besides professional activities, many people rely on social media to seek emotional support when going through career-driven hardships, such as unemployment [57, 99]. In online settings where there is greater anonymity, individuals are likely to disclose personal and sensitive information related to physical and psychological health, which they might not otherwise freely reveal to their friends, colleagues, or managers [55]. While people may be reluctant to self-disclose health-related matters (including mental health), employers and organizations need to be cognizant of workers' well-being concerns [35]. At the individual level, health problems can affect many aspects of one's life, including mental health [128], physical health [136], and lifestyle [68]. At the organizational level, health problems in the workforce can lead to reduced productivity, lower work quality, and turnover, which can introduce tangible and intangible costs to organizations [85].

Understanding workers' challenges and well-being in the context of the labor market has been a key topic of interest in Social Computing communities. Previous research in these fields has examined the impacts of technology and **Artificial Intelligence (AI)** on future employment [22, 174], workforce stress level [113], and work-life balance [74], just to name a few. Additionally, researchers have explored well-being differences across various socio-demographic groups, such as gender, age, and race [9, 10, 167]. For instance, previous research [83] found that regularly working from home can increase daily fatigue and work-to-family conflict for women more than for men, whereas the ability to take time off during the day for personal reasons can reduce job stress for both genders. The results of another study revealed that there were differences in the levels of occupational stress experienced by **Information Technology (IT)** workers of different ages, with younger individuals reporting higher levels of stress than older ones [84].

Previous studies on worker well-being have mainly relied on self-reported data collected through surveys and questionnaires [9, 18, 121]. Collecting such data is costly and time-consuming when conducted frequently, resulting in limited temporal granularity for timely interventions [181]. Additionally, due to the cost and complexity of these methods, surveys are often administered to small samples that may not represent marginalized groups. As a result, findings based on these samples may not generalize to broader populations [32].

Inspired by growing interest in workers' challenges in a fast-evolving labor market, we assess workers' well-being across topics such as job search and skill development using large-scale social media data. Although our work is motivated by broader discussions of the Future of Work shaped by technological change, our empirical analysis centers on Reddit discussions of IT-related skills, occupations, and labor-market experiences, rather than on artificial intelligence technologies themselves. More specifically, we study the well-being of workers in the IT-related fields, also known as "information workers", who are among the most stressed [121]. Information workers are those who deal with data and information to perform their daily jobs, e.g., software engineers and business analysts, "*instead of dealing with physical objects of labor*"¹. The broader objective of our work is to examine how online social network data can be used to understand the challenges faced by information workers and how such challenges relate to their well-being. On this basis and using over 700,000 unique Reddit posts related to the IT domain, we address the following research questions:

- **RQ1:** *What labor market-related issues are information workers expressing in online communities?* To address this question, we develop a codebook representing labor market topics in the collected Reddit data. We use this codebook to identify labor market topics in online posts.

¹<https://www.igi-global.com/dictionary/information-worker/14587>

- **RQ2:** *What are information workers’ well-being concerns that are shared in the labor market content posted in online communities, and how are they expressed, when considering gender and age groups?* We utilize **natural language processing (NLP)** techniques to infer workers’ gender and age. To assess how workers’ well-being varies across gender and age groups, we examine linguistic and psycholinguistic differences in labor market-related discussions.

The findings of this study can inform human resource policymakers in both academic and industry settings by highlighting challenges experienced by workers in the knowledge economy, including differences across gender and age groups. By leveraging insights derived from online discourse, organizations in the IT sector can more proactively develop policies and interventions that help workers manage stress, support well-being, and improve job performance.

This article makes the following contributions:

- (1) We identify the types of support information workers seek in online social communities and quantitatively analyze labor market-related challenges expressed across career stages, gender, and age groups.
- (2) We characterize information workers’ concerns and psychological well-being across demographic groups through linguistic analysis of online community discussions.
- (3) We situate our findings within prior research to assess their consistency with established empirical studies.

Privacy, Disclosure, and Researcher Perspectives. Our research team comprises researchers holding diverse gender, racial, and cultural backgrounds, including people of color and immigrants, and holds interdisciplinary research expertise in social computing and related fields. This work utilizes public data available on Reddit without direct interaction with users; however, to protect the privacy of the individuals in our dataset and prevent reverse identification, we anonymize all usernames. To reduce traceability while still providing adequate context for our findings, we also paraphrased authors’ quotes and deleted any individually identifying information when reporting quotes in this article and elsewhere. We acknowledge that in this study, we only considered users who identify themselves as female or male, disregarding a wider, more inclusive spectrum of gender identities. Further significant effort has to be made to protect marginalized communities from harm and to accommodate a wider variety of gender identities. We provide a more detailed explanation of the ethical and privacy considerations in Section 6.

2 Related Work

2.1 Psychological Well-being of Workers

One of the important factors to consider when studying labor market dynamics is its impact on workers’ well-being. Well-being is a diverse concept that interconnects one’s physical well-being, psychological well-being, and mental health [3]. According to [75], workers’ well-being is “*that part of an employee’s overall health that they perceive to be determined primarily by work and can be influenced by workplace interventions*”. Understanding workers’ well-being is essential due to the tangible and intangible benefits that it has for employees and their employers. For example, prior studies showed a significant positive relationship between workers’ well-being and their productivity and a negative relationship with employee turnover [92]. As such, a growing research direction is focused on studying workers’ well-being [29, 132, 142, 146, 165]. For instance, prior studies have shown that technological advancements enable workers to have a flexible work environment that gives employees control over where and when they work, which positively correlates with their well-being [74, 87]. Other research has explored the negative effects of information and communication technologies on workers’ well-being, especially work-related stress. For instance, technology can noticeably increase the mental load of individuals. For example,

employees' inability to unplug themselves from work leads to a blurred boundary between work and life [166].

More specifically related to IT job settings, various researchers have focused on understanding information workers' stress, mood, and cognitive load under differing circumstances, e.g., during a technical job interview [13, 121]. For instance, [9] explored whether the well-being of IT employees is different across age and gender groups.

Considering workers' well-being has received special attention in recent years [23, 26–28, 30, 31, 60, 77, 99, 134, 140, 165, 182, 183]. Notably, [76] evaluated the discrepancy between employees' subjective well-being and their objective well-being. The authors collected self-reported data related to emotions from 15 IT workers through a diary study every half an hour, and employees automatically labeled emotions using their facial expressions by utilizing an **Automatic Emotion Recognition (AER)** tool every microsecond. The results showed the inadequacy of AER tools for correctly detecting employees' emotions without considering self-reported emotions. These authors further analyzed emotional differences between men and women and found sadness to be the dominant emotion for women compared to men, who expressed a combination of emotions, such as happiness, sadness, and anger, in their diary self-report emotions.

2.2 Assessing Workers' Well-being via Social Media

People across the globe use social media to express their emotions, share information about their health, seek social support, and record their interests, among other activities [63, 143]. Evidence suggests that an increasing number of people rely on the Internet to gain information related to mental health and well-being [5, 127]. However, a recent systematic review states that online user-generated content is still a novel technique for evaluating people's well-being, which is receiving growing attention in recent years [148].

Research has examined the effectiveness of online social media data in understanding mental health self-disclosure concerning psychological stress [63, 139], self-harm, e.g., suicide [152], anxiety [44], and depression [64, 66], to name a few. For example, [145] utilized X (formerly Twitter) data to quantitatively measure the impact of the COVID-19 pandemic on people's mental health by exploring how one's psychological concerns have evolved during the pandemic. [173] collected tweets posted by college students in different universities located in the United States to shed light on the mental well-being of students by analyzing how they express their needs and concerns. [111] took one step further and provided insight into the topical and linguistic features that can help understand mental health by leveraging Facebook private messages. Other researchers have also validated the effectiveness of social media data for predicting the mental health of individuals [146].

In the context of the labor market, prior studies have utilized social media data to examine well-being and mental health on a variety of topics, such as unemployment [57], job satisfaction [147], organizational culture [165], and role ambiguity [142]. For example, [181] measured and predicted job burnout on a Chinese social media network called Weibo. The authors explored the relationship between job burnout and users' linguistic and semantic preferences in content posted on Weibo, the frequency and timing of the posts, and finally, the interaction between each user and their network. The authors' findings suggest that before the burst of burnout, workers generated more content, and their language styles, such as terminology selection, were different from other groups without experience of burnout. [57] applied a mixed methods approach to model topics expressed by workers on Reddit about unemployment and explored the emotions that workers revealed for each topic.

2.3 Technologies and Digital Data to Support Workers' Well-being

Social support can help people overcome difficult situations, which positively impacts individuals' well-being [47, 157]. Interviews of 28 individuals who went through major transitions, e.g.,

relocation, job loss, or career change, revealed that the support received from unknown networks was more effective than the support provided by known ties [185]. Through a mixed methods study consisting of a survey and semi-structured interviews, [42] showed the important role of community support in up-skilling, job search success, income improvement, and well-being enhancement of those who were experiencing financial hardships and poverty. Similarly, [69] emphasized the relationship between social support and success for those under-resourced entrepreneurs who feel the need to conduct their business using digital tools. Other scholars have designed a variety of tools to provide social and emotional support for community members in an automated way to improve their well-being [110, 161, 175].

Research has also investigated the importance of social and emotional support on workers' well-being [62, 88, 149]. An investigation including 867 IT professionals revealed that support from managers for their workers' job autonomy, e.g., to work remotely, greatly reduced workers' psychological and physical distress [112]. Other scholars have emphasized the role of social support during workers' different life stages, such as lifelong learning [91], unemployment [99], and post-college transition [60]. With the increase in the popularity of online social media, researchers have explored the utility of online communities as a source of social support [7, 82]. For example, [127] applied a mixed-method approach to explore how young people leverage the Web to seek help. [186] utilized machine learning and psycholinguistic analysis techniques to investigate veterans' needs and the type of support they receive from an online community.

2.4 Automated Detection of Social Media Users' Psychological Well-being

In contrast to the work mentioned earlier on workers' well-being, another strand of research focuses on applying machine learning methods to identify and classify online content regarding users' psychological well-being [8, 71, 72, 78]. For example, [157] explored the congruence between community mental support and users' linguistic alignment. To identify the expressed mental health issues, the authors applied a clustering technique called k-means on Reddit data to detect the overall psychological issues, followed by a semi-open coding technique to verify and label the groups. To detect tweets with self-disclosure information about schizophrenia, [157] applied NLP to detect posts with explicit mentions of schizophrenia disorder, i.e., being diagnosed with schizophrenia. Then, they trained machine learning models to expand their dataset by classifying more posts within these mental health categories.

Since machine learning-based methods are often data-hungry and require labeled data, another widely used technique in this space is the utilization of psychological lexicons, such as **Linguistic Inquiry and Word Count (LIWC)**, which allow for the curation of large-scale labeled datasets [150]. For example, [57] applied an emotion lexicon to detect emotions such as sadness, embarrassment, and rejection among Reddit users in the context of unemployment. Other researchers detected psychological stress, i.e., anxiety, frustration, and anger, using Reddit, Facebook, and X via a lexical list of terms [60, 63]. [158] combined lexicon-based features of LIWC and N-grams ($N = 1, 2$) to train machine learning models to predict possible anxiety disorders of Reddit users. For instance, [144] used LIWC features and machine learning to study how community support affects users' psychological change on Talklife, and [186] applied LIWC to analyze Reddit posts and identify Veterans' needs and the support they received from the community.

3 Collecting IT-related Data from Social Media

This article studies information workers' well-being as expressed on a community-based social network, namely Reddit. Reddit is one of the largest online communities, with more than 100 thousand active forums and over 22 billion posts and comments as of December 2024.² One of

the contributing factors to the popularity of Reddit is that users can anonymously express their opinions on a given topic [6]. Users are afforded a lenient character limit per post (up to 40,000 characters), significantly more than other social media platforms, such as X [158]. Additionally, Reddit data can be easily analyzed using an official API [91] or the Pushshift Reddit dataset [11]. Therefore, many scholars rely on the rich user-generated content from Reddit to answer various questions, from mental health [33, 139, 141] to the labor market [55, 57, 105, 106]. Similar to prior studies, we leverage Reddit data to address the research questions described in Section 1.

To collect Reddit data for this study, we first curated the list of IT skills from the **International Standard Classification of Occupations (ISCO)**, which is a tool for global labor market reporting [12] (Table 1). Then, we downloaded Reddit posts from Pushshift,³ which were posted between January 2015 and August 2019. The Pushshift dataset, which is frequently updated, provides a comprehensive archive of Reddit data that contains posts and comments from almost all public subreddits since 2005 [11]. Unlike Pushshift, accessing historical data is not possible through the official Reddit API. While Pushshift also provides an API, we downloaded monthly dumps of data to avoid a delay in data collection due to the query limit imposed by the Pushshift API. Next, we conducted text pre-processing on the obtained data to optimize retrieval effectiveness based on the collected IT skills. This included lowering the case, deleting stop words, and stemming. Note that, we only included Reddit posts that were written in English and contained one of the IT skills keywords in their title or body and did not have the tags “deleted” or “removed”. We also removed posts from the same author, title, and body of the post. The above steps led to a collection of posts in all subreddits that contained at least one of the IT-related keywords. Then, through an iterative process involving extensive re-evaluation, we curated a list of subreddit names primarily featuring posts related to technical skills. We then removed subreddits exclusively dedicated to news, academia, or recruitment, and non-technical topics such as “r/relationship,” “r/depression,” and “r/starwars”. As a result, we collected 787,398 unique posts in 546 subreddits, posted by 417,983 unique users. We provide more details on the motivation behind our data collection strategy in Appendix A.

3.1 Characteristics of the Reddit-derived Sample Using Observable Proxies

Because Reddit does not provide demographic metadata, we assess the composition of our sample using observable behavioral and contextual proxies. Table 2 summarizes key properties of our

³<https://files.pushshift.io/>

Table 2. Characteristics of the Reddit-Derived Sample Using Observable Proxies for Representativeness

Dimension	Proxy Used	Distribution in Dataset	Interpretation
Subreddit type	Topical clustering of communities	45% learning-oriented; 30% professional technical; 20% specialized domains; 5% consumer technology	Coverage of multiple career stages and technical roles; primarily work-related discourse
Posting volume	Posts per user	Mean = 1.88; 85% (1–2 posts); 13% (3–10); 2% (>10)	Highly skewed participation is typical of large online communities
Participation breadth	Unique subreddits per active user	Mean = 3.11; Median = 3	Indicates cross-community engagement across technical topics
Engagement level	Comments, and score per post	Median comments = 7; Median score = 4	Posts generally received interaction, indicating visibility and relevance
Geographic proxy	Self-disclosed location (n = 1,500 sample)	10% North America; 3% Europe; 1% Asia; 1% South America; 85% unknown	Suggests North American and English-speaking bias

dataset, including topical communities, user activity levels, engagement, and available geographic signals.

To approximate occupational coverage, we grouped subreddits into four high-level topical domains that correspond to segments of the IT ecosystem: learning-oriented communities, professional technical communities, specialized technical domains, and general consumer-technology forums. Learning-oriented communities, including programming education and introductory forums, constitute the largest share, approximately 45%, indicating strong participation from students and early-career workers entering the IT pipeline. Professional technical communities, 30%, cover software development, IT operations, cloud infrastructure, and data science, suggesting substantial representation of practicing professionals. Specialized domains, 20%, capture fields such as cybersecurity, mobile development, hardware engineering, game development, and UX/design, reflecting niche expertise areas. General consumer-technology forums, 5%, are comparatively small, implying that discussions are primarily related to work rather than hobbies. In general, this distribution mirrors the layered structure of the IT workforce, which includes trainees, practitioners, and specialists.

User activity was measured using posting volume, participation breadth, and engagement outcomes. For each author, we computed total posts, the number of unique subreddits participated in, and cumulative engagement metrics (comments and scores). The distribution is highly skewed toward low-frequency contributors: 85% of users posted one or two times (casual contributors), 13% posted 3–10 times (moderately active), and 2% posted more than 10 times (highly active). The mean number of posts per user is 1.88, consistent with the participation inequality observed in large online communities. Moderately to highly active users participated in an average of 3.11 unique subreddits (median = 3), indicating cross-community engagement rather than confinement to a single forum. Engagement metrics show that posts typically elicited community response (Median comments = 7, Median score = 4), suggesting that discussions were visible and interactive rather than ignored content.

Because explicit location data are unavailable, two researchers manually examined a random sample of 1,500 posts for self-disclosed locations. Among identifiable cases, approximately 10% referenced North America, 3% Europe, 1% Asia, and 1% South America; the remaining 85% contained no geographic information. The predominance of North American references aligns with publicly

reported platform demographics⁴ and the English-language nature of the sampled communities. Consequently, the dataset likely overrepresents English-speaking IT workers and underrepresents regions where Reddit usage is lower.

These proxies suggest that the sample captures multiple strata of the information workforce—trainees, general practitioners, and specialists—rather than a single niche population. The strong presence of learning communities corresponds to the large global pipeline of aspiring developers, while the substantial share of professional and specialized forums reflects established roles across software engineering, infrastructure, and security. However, the North America-leaning geographic signal and voluntary participation imply potential biases toward workers comfortable discussing workplace issues publicly in English. We, therefore, interpret the dataset as broadly representative of the online IT discourse ecosystem rather than statistically representative of the global IT workforce. Limitations and implications for generalizability are discussed in Section 6.4.

4 Research Question 1: Modeling and Analyzing Information Workers’ Challenges on Reddit

4.1 Identifying Labor Market Topics on Reddit

To identify the topics discussed in Reddit posts, as suggested in [89, 91, 95], we created a codebook following a bottom-up process called *inductive coding* [168]. The inductive approach is a qualitative coding process where the topics are derived from raw data by a close reading of the text [168]. Using this approach, researchers can iteratively and systematically create and refine conceptual categories until they adequately represent the thematic view of the observed data [21, 170]. We randomly sampled 500 Reddit posts out of 787,398 to develop the codebook. Then, two researchers individually coded each sample in the 500 posts based on their understanding and wrote a definition for each observed code. In approximately 20% of the cases, the researchers assigned two codes to the text when they identified the presence of more than one topic. Then, the two researchers sat together and went through each of their codes in detail. As part of this process, they re-assessed their codes and grouped some conceptual categories to represent a broad category. After this step, only one code was assigned to each post. This step led to a preliminary codebook that reflected labor market-related topics.

After forming the conceptual categories, the researchers verified the obtained codebook by coding another 50 Reddit posts. A list of these codes and a detailed description of them can be found in Table 3. Finally, the two researchers coded another 450 sampled random posts to assess how similar their interpretations were. In doing so, a high average Cohen’s Kappa coefficient of 0.91 was obtained. Using this codebook, the two researchers manually coded a random sample of 1.5% (11,854) of the entire dataset. When researchers were unsure about a specific label for a post, they debated the options. We report the frequency of observed topics in the labeled dataset in Table 3. While our data is dedicated to IT topics shared in more than 400 subreddits, we find similar topics to those found by [57] on “r/Jobs” and “r/GetEmployed” subreddits. To investigate whether IT workers’ challenges remain the same or change over time, we applied the same steps to data from a different time frame. The results from this analysis are reported in Appendix B. We then used the qualitatively coded data to build machine learning classifiers to label the remaining 775,544 Reddit posts in our dataset. The details of these classifiers are described in the following section.

4.2 Building a Machine Learning Classifier of Labor Market Topics

To extract the labor market topics in Reddit posts at scale, we built machine learning classifiers on the annotated dataset. As shown in Table 3, we observed that the most frequent topics in our

⁴<https://www.alphr.com/demographics-reddit/>

Table 3. Codebook of Common Topics Derived From Reddit Posts Discussing IT-Related Topics

Topic	Definition	Example Posts
Skill Development	Gaining popular skills and degrees in the labor market; offering people help in skill development or picking up a new tool; posting about how endless the field is, and how much there is to learn.	The website I designed looks like shit, how do I improve it
Job Application/Job Search	Looking for resources to help with job searching, such as networking opportunities; seeking suggestions and feedback for enhancing resumes or interview techniques; things to do while searching for a job, such as volunteering.	I'm very anxious about getting my first programming job. Any advice or resources to help me get started
Education	Seeking advice for a university major/minor; Changing fields of study; discussing the cost of education; seeking advice on persuading more degrees, i.e., a Ph.D.; getting advice on getting back to school, obtaining the required skills to enter grad school; complaining about a degree/school; grades/school failure stories; discussing admission to the university; admission applications; how to improve in university to find a job.	If you're paying for graduate school in a STEM field, you're doing it wrong. I think I might be doing it very wrong, help [..]?
Employment/Job Concerns	Wages vs. work effort; hostile/unethical work environments and strategies for improving them; job burnout and decreased job satisfaction; benefits; work-life balance; underpayment; conflict with co-workers over technical ideas; people who got fired and talk about their experience (not currently doing a job search); getting hired for one position but being asked to take on other responsibilities.	Work a steady IT job but a miserable creative
Decision Making	Making career decisions and finding light when they are lost; coming up with a name for a job title if already employed; getting a job or academic degree; finding the education path that leads to the best career option in the future; making decisions on whether to leave a job for another when the job offer is received; accepting a job offer or rejecting it.	What career(s) involve problem-solving in politics?
Career/Industry Change	Thinking about changing the current job due to personal reasons; seeking advice to change the current industry; learning new skills to change a career; catching up with new skills to switch jobs; discussing resignation when there is already a job offer to change the job.	Considering a career switch, currently overwhelmed and underpaid.
Technical Challenges	The problems that learners or workers face in learning or applying a skill.	Problems booting HDD - Linux noob needs help.
Qualification	Being over- or under-educated/experienced; Not being able to apply/perform jobs because of a lack of certain skills; discussing mentioning imposter syndrome; feeling unqualified to apply for other jobs or enter the job market; worrying about getting poor performance reviews as a result of bad work; worrying about skill transfer if I switch to another job.	I failed college, am kinda lost, and have no job. Any advice?
Health	Posts related to information workers' mental and physical health.	A three-time college dropout, anxiety troubles, and feeling apprehensive about the future.

Table 4. Performances of the Best Machine Learning Model for the Topic Classification Task Based on the F1-Score

Topic	Precision	Recall	F1-Score
Job Applications/Job Search	0.77	0.78	0.77
Skill Development	0.84	0.85	0.85
Employment Concerns	0.73	0.83	0.78
Education	0.79	0.79	0.79
Other	0.91	0.87	0.89
Weighted Average	0.85	0.85	0.85

The weighted average for all the topics is reported at the end of the table.

collected IT-related posts were “Skill Development”, “Job Application/Job Search”, “Education”, and “Employment/Job Concerns” with 32.47%, 17.75%, 12.57%, and 11.80% frequencies, respectively. Although all identified topics are equally important in understanding information workers’ needs and concerns, since machine learning models are data-hungry and not all topics had sufficient sample size, we had to focus on the ones with a satisfactory amount. Therefore, we trained our machine learning models on these four topics.

To select the best-performing machine learning classifiers, we explored different classifiers, such as **Logistic Regression (LR)**, **Random Forest (RF)**, and **Linear Support Vector Classifier (SVC)**. We trained these models on **term frequency-inverse document frequency (TF-IDF)** vectors of Reddit post titles and bodies. The GridSearchCV from the Sklearn library was used to tune the hyperparameters. Additionally, we fine-tuned bidirectional transformers, such as BERTbase (12-layer, 768-hidden, 12-heads), and XLNetbase (12-layer, 768-hidden, 12-heads), which are already trained on a large corpus of English data. To fine-tune BERTbase and XLNetbase, we set the batch size to 16, the learning rate to $2E-5$, maximum sequence length to 512, and used the ADAM optimizer. We utilized a k -fold ($k = 5$) *cross-validation* approach on our labeled data (11,854 posts) to assess the performance of our classifiers. Table 4 reports the accuracy metrics of the best-performing classifier. The XLNet classifier performs the best in predicting each topic and has the best overall accuracy (F1-score = 0.84). By comparing our results to similar studies that trained machine learning classifiers to explore a variety of phenomena using online data, we noticed that the accuracy of our best model is within the range of [70-90], which is the median reported performance in the literature by prior scholars [32, 157, 181]. For example, the accuracy of the neural-based model in identifying user engagements on Amazon.com and TheGuardian were reported at 0.76 and 0.71, respectively [131]. Similarly, [141] achieved a median precision of 0.75, a median recall of 0.74, and a median F1-score of 0.75 in an attempt to train a binary Neural Network classifier to detect the Reddit posts that contained any sign of stress from members of the LGBTQ+ group.

We use XLNet to label our entire dataset. We summarize the performance metrics of the other trained models in Table 15 (in the Appendix). By applying XLNet, 6.60% (51,987 out of 787,398) of posts were labeled as Skill Development, 2.3% (18,061 out of 787,398) of posts were labeled as Job Applications/Job Search, 2% (15,600 out of 787,398) of posts were labeled as Education, and 0.53% (4,198 out of 787,398) of the posts were labeled as Employment/Job Concerns. The rest were labeled as “other”.

4.3 Detecting Information Workers’ Themes around Most Discussed Topics on Reddit

As discussed in Section 4.2, most information workers posted about four major topics, namely, Skill Development, Job Applications/Job Search, Education, and Employment/Job Concerns. In this section, we systematically review information workers’ themes around the most discussed

Table 5. List of Labor Market Topics and the Most Discussed Terms in Each Topic across Our Reddit Dataset Expressed by Information Workers

topics on Reddit. To get insight into the themes identified in the Reddit posts, we first conducted an exploratory data analysis. To do so, we first applied an unsupervised phrase extraction technique, namely the **Rapid Automatic Keyword Extraction (RAKE)** algorithm [135], to retrieve the most frequently mentioned phrases within the Reddit posts. We reported the top-mentioned phrases in each topic in Table 5. Based on Table 5, we noticed that some of the most frequent terms, i.e., “learn”, “start”, “job”, and “experience”, are common in all of the labor market topics. However, some terms were highly discussed in particular topics. For example, “team”, “people”, and “busy” were

the most frequent terms in the Employment/Job Concerns topic, while “research”, “university”, and “graduate” were discussed the most in the Education topic.

To comprehensively examine the key themes that are present in each topic, we applied a mixed methodology. First, we extracted all n -grams ($n = 2,3$) from Reddit posts in each labor market topic along with their $tf-idf$ score. Then, we performed an unsupervised clustering technique, namely K-means [65], to aggregate the n -grams into groups based on their content similarities. Then, two researchers reviewed a 5% random sample of the Reddit posts that contained any of the n -grams in each group and discussed the theme that the posts presented. The final themes and the top n -grams that represent each theme in each labor market topic are illustrated in Table 6.

By analyzing the explored themes in Table 6, we noticed the prevalence of learning discussions in all labor market topics among information workers. This prevalence is consistent with prior research highlighting the enduring popularity of learning in this context [105]. We observed that these posts were mainly written by workers who were either in the process of entering the job market or were already employed and were looking for resources and tips to upgrade their skills. For example, one of the workers who was looking for a job as a computer programmer wrote “*I have a degree in criminology, but I am learning to program from home [...]*”. Another worker who discussed Employment/Job Concerns wrote “*I work in a company with a tight budget. My supervisor asks me to take the time to learn and understand what I’m doing, but we are low in staff, and I don’t have time for learning and improvement [...]*”. Such examples highlight the importance of learning in the labor market.

As mentioned by prior researchers, workers in the knowledge economy are required to be lifelong learners who continuously learn, re-learn, and unlearn to stay employable and in demand [106]. Lifelong learning is a continuous process that happens everywhere in different contexts throughout life in a formal or informal setting [51]. Formal learning relates to a structured educational model designed and run by a predetermined curriculum in a setting that requires students, teachers, and institutes where certification or degrees will be issued upon completion of the program [37]. In our dataset, the Education topic represents content around formal learning activities. Informal learning, which is 70–90% of human learning, occurs outside institutes, e.g., through workshops or training, where students do not need to interact with teachers, duration, and goals might vary, and a certificate may or may not be given [93]. In our dataset, the Skill Development topic refers to the posts generated by information workers focused on obtaining a new skill through informal learning. Thus, even though the issues of education and skill development are unique since they both include different kinds of lifelong learning activities, it is logical that learning would be the subject that receives the most attention in both.

The reported themes in Table 6 revealed that the inquiries related to the Skill Development topic were focused on finding the next best course/topic to learn and tips on how/where to learn a particular skill. For example, one of the workers who was trying to find the best place to learn a skill wrote: “*I have a full-time job but I’d like to learn programming in my spare time. I want to start with MySQL/Python and then C. Where can I learn this? online courses? evening classes?*”. Also, many workers complained about being lost when trying to find a good starting point. For instance, one of the workers in the process of learning mobile development wrote: “*I’m struggling with where to begin [...] Am I correct in thinking this is just too much to learn in too little time? [...] I’ve spent all morning just trying to figure out how to add a button, but I’m afraid to touch anything*”.

The themes in the **Education** topic indicated that the majority of the workers required help from online communities to find the right major/minor programs that would help workers find their desired jobs or pursue further degrees. For example, one of the workers wrote “*should I pursue a master’s degree in robotics and intelligent systems alongside my wife’s pursuit of a Ph.D. or prioritize job stability and remain in my current role as a controls engineer?*”. We also observed that workers

Table 6. *N – grams* that Represent the Most Discussed Themes in Each Labor Market Topic

Topic	Final Theme	Top <i>n – grams</i>
Skill Development	Finding the next best course/topic to learn	programming language learn, best programming language, learn web development, learn new language, html cs javascript, coding boot camp, need help finding, ai machine learning, learn machine learning, improve programming skill, help getting started, asp net mvc, learn programming language, need help choosing, learn asp net, good starting point, language start learning
	Tips on how/where to learn a particular skill	best way learn, help finding good, good way start, good way learn, good stepping stone, good starting point, good resource learning, invest time learning, improving programming skill, improve python skill, improve problem-solving, important thing learn, good place learn, good programming book, need help learning, best place learn
Job Application/ Job Search	Job interview process	interview coming week, got technical interview, resume cover letter, position require year, second round interview, cracking coding interview, received job offer, final round interview, big tech company, require year experience, start building portfolio
	Professional and educational background	background computer science, recently got accepted, mid-level developer, going grad school, college couple year, pursue graphic design, previous work experience, bachelor degree computer, work large company, computer science internship, went community college, work data scientist, graduated bachelor degree, graduated college degree
	Learn Skills to land a better job	data science course, learning web dev, learning basic python, started learning, computer science class, good starting salary, good stepping stone, considering going school, feel like learned, graphic design skill, new programming language, learning web development, learning html css
	Work-life balance	work-life balance, good work life, working hour week
Education	Finding the right major/minor programs that would help workers find their desired jobs	need help deciding, considering going school, entry level position, like computer science, computer engineering major, year computer science, computer science major, computer science job, computer science school, interested computer science, considering applying PhD, chance getting job, land good job, learn computer science, time finding job, bachelor degree work, time job work
	Learning a new subject	statistic machine learning, started learning programming, learn programming language, learning data structure, taking programming class, feel like learning, intro programming course, learn computer science
	Pursuing further degrees	dual degree program, going graduate school, plan getting master, engineering master degree, straight master program, master program accounting, pursuing double major, master program worth, feel like pursuing, going grad school, applying phd program, accepted master program, online master program, apply master program, second bachelor degree
Employment/ Job Concerns	Decide whether they should stay in or leave their current job	feeling bit lost, finding new job, getting taken advantage, good career path, got great job, got job offer, got new job, got offered job
	Micro-management	micromanagement, title change, direct boss, rebooted, yelling, annual review, old boss, good guy, taken advantage, getting fired, deaf ear, entire office, boss say
	Working overtime	hour work week, hour week working, long period time, work overtime
	Learning	learned html cs, learning html cs, learning new language, learning new technology, learning new thing, like learning new

engaged with online communities to ask for support and advice regarding future employment. For example, in the **Job Search/Job Application** topic, workers mainly asked questions or shared their personal experiences about their job interview processes, their professional and educational background, the skills that they need to learn to land a better job, and the work-life balance that their current job provided versus the ones that they were looking for. We also noticed that workers who successfully landed a job discussed important hints about their career, managers, colleagues, or the projects that they were assigned in the **Employment/Job Concerns** topic. Some workers posted on Reddit when trying to decide whether they should stay in or leave their current job, and some workers disclosed information about micro-management and working overtime. For example, one worker in a post related to Employment/Job Concerns complained about the vagueness of their job description, which caused stress and anxiety, and the lack of support they received from their manager in this regard: *"I feel like not fully understanding my scope has caused a lot of stress. I have mentioned not understanding my scope to my manager and my team, but I received no help or support. Now my manager is on leave, and everything is placed on me. There is zero documentation and no help, and I am afraid of getting fired [..]"*. These examples and the most discussed issues reported in Table 5 point to some of the top challenges faced by information workers in the fast-changing labor market, which are consistent with earlier research on the challenges of workers who are learning new skills through formal education or self-learning [60], those trying to enter the job market [13, 178], or workers who are already employed [142, 160].

5 Research Question 2: Well-being Concerns and Their Expression across Information Workers' Genders and Ages

In the second research question, we examine information workers' well-being concerns as reflected in their posts and compare their linguistic characteristics across different gender and age groups. We specifically study linguistic differences in terms of two sub-research questions, namely, (RQ2.a) language differences, and (RQ2.b) psycholinguistic differences. We will elaborate on how these differences are estimated and our findings in the following sections. Detailed explanations of how age and gender were extracted can be found in Section 5.1. We acknowledge that there are limitations in how we identified workers' genders and ages, which we discuss in-depth in Section 6.3.

5.1 Retrieving Information Workers' Age and Gender from Reddit

Users are not required to disclose their socio-demographic data, such as gender, age, race, or occupation, on many online social platforms. For example, users can sign up on the Reddit platform by only providing their e-mail, a username, and a password. Researchers have applied various techniques to study the role of socio-demographic attributes in different phenomena using social media data. For example, to study whether females and males promote themselves differently on LinkedIn, Altenburger et al. [4] used predicted gender labels from users' profiles. Tifferet et al. [169] classified LinkedIn users as female or male based on their profile pictures. To study social media data about users' demographics, other researchers collected social media users' demographics such as age, gender, race, and income through a questionnaire [59, 63]. In a recent study, [130] identified gender by leveraging a set of keywords that represent females and males, such as "her", "mother", "woman", and "fiancee" for females and "he", "son", "father", "finance", and "brother" for males. [16] used labeled data as a training set to retrieve the gender of unlabeled data using deep learning classifiers, such as BERT and XLNet. According to [16], the fine-tuned BERT model can show reliable gender prediction results in the context of information retrieval. It's important to note that the proposed methodology by [16] is used when there is no explicit mention of gender in the data. Also, since the dataset from [16] consists of queries and passages taken from internet pages or social media, their suggested methodology may be used in social media studies when

Table 7. Performance of the Fine-tuned BERT Uncased Model for the Gender Retrieval Task

Gender	Precision	Recall	F1-Score
Female	0.90	0.92	0.92
Male	0.91	0.91	0.91
Neutral	0.92	0.90	0.91
Mean	0.91	0.91	0.91

there is no direct mention of gender. Therefore, in our study, to retrieve information on workers' gender, we applied a similar methodology to [130] and [16] on our own data to curate a training dataset and extract gender, which we will explain in the following sections.

By analyzing Reddit posts, we noticed that while individuals have the option to withhold their gender when creating an account on Reddit, some workers decide to declare this information in the title or body of their posts when reaching out to online communities. To do so, workers include [F] or [M] in the title or phrases such as "I am a woman" and "I am a man" in the body of their posts to identify themselves as female or male, respectively. Therefore, to identify information workers' gender in our dataset, we first applied regular expressions to select the posts that explicitly mentioned one's gender either in the Reddit titles or the body of the posts. For example, we extracted posts with keywords such as "m", "male", "man", "f", "female", and "woman", where all Reddit content is lowercase. Through this approach, we extracted 512 posts as male users, 3,856 posts as female users, and 783,030 posts as others. To verify that the posts obtained through the rule-based approach indeed contained self-disclosed information about the user's gender, either male or female, one of the authors manually read the Reddit posts in the male category and confirmed that 457 posts explicitly stated the user's gender as male. However, although the remaining 55 posts contained male references, there was not enough evidence to suggest that the user revealed their gender. Therefore, those 55 posts were categorized as neutral (we use the word neutral to mean that gender was unknown). To ensure our dataset was balanced, the same author randomly sampled 1,000 posts from the female category, of which 470 contained self-identified information about being female and 530 included female references, but the explicit mention of the users' gender was missing. Therefore, those 530 posts were categorized as neutral. We then used this gathered data to fine-tune a BERT model [36] with a batch size of 16, a learning rate of $3E-5$, 15 epochs, and the Adam optimizer. We assessed the performance of this model by applying a k-fold ($k = 5$) cross-validation technique. We report the performance of this model in Table 7. As shown in Table 5, the overall performance of the model and also per gender is 91%. We used this model to retrieve gender from the 89,846 posts introduced in Section 4.2. As a result of this process, we obtained 5,847 posts submitted by female workers, 23,105 by male workers, and 60,894 posts as neutral (or undecided). We present the breakdown of the gender in each labor market topic in Figure 1.

Similar to the gender retrieval task, scholars have tried to detect the age of users in social media posts using a variety of methods, such as traditional machine learning models and deep learning techniques [1, 56, 114]. However, a literature review conducted by [118] on age and gender prediction methods revealed that age prediction using language features of social media leads to a lower performance than gender prediction. For instance, by applying deep learning algorithms on X data, [176] could only achieve a 0.52 accuracy on the multi-class age prediction task, while the performance of their model was over 0.91 for the gender prediction task on the same data. Therefore, to retrieve the age of the information workers who talked about one of the labor market topics in our 89,846 posts dataset, we applied regular expressions to only retrieve those Reddit posts that explicitly used phrases, such as "25 years old", "M/23", "I'm 45 Y", and "I turned 30", to

Fig. 1. Distribution of recruitment topics by retrieved gender (normalized). Light bars represent female users, and dark bars represent male users.

Fig. 2. Distribution of age in different groups.

name a few. In other words, instead of predicting the users' age, we only relied on the posts with explicit mention of the users' age to avoid fabricated prediction results in our analysis.

According to a report by Agrawal⁵, 8% of the Reddit population are individuals between the ages of 13 and 17, 45% are between 18 and 29, 40% are between the ages of 30 and 49, and 7% are above the age of 50. Inspired by these statistics, for our analysis, we used similar groups except for breaking the 18–29 age bracket into two groups: individuals between 18 and 24 in one group and individuals between 25 and 29 in another. The PWC Global Workforce Hopes and Fears survey,⁶ which revealed that employees between the ages of 18 and 24 had distinct demands and expectations compared to workers belonging to other age groups, had a significant impact on the decision to divide the 18–29 age group into two units. Additionally, we noticed that in our dataset, only 0.2% of the posts were written by users in the 50–64 age category, and 0.02% were written by users above the age of 65. As a result of insufficient data quantity for older information workers, we merged those categories, and we only reported them as above 30. Using this approach, we extracted 11,910 posts containing age information. We report the age distribution for each group in Figure 2. We further present the breakdown of the age in each labor market topic in Figure 3.

To validate the gathered data, one of the researchers randomly selected 500 posts, 100 posts in each age group, and manually labeled them. As a result, we obtained an overall average accuracy of 88.2% (below 18: 76%, 18–25: 91%, 25–30: 89%, above 30: 88%, and unknown: 97%). To evaluate the potential selection bias introduced by demographic self-disclosure, we compared observable behavioral characteristics between posts containing self-disclosed gender information and posts without such disclosures. Engagement metrics show broadly similar interaction patterns across

⁵[https://medium.com/\\$@\\$sm_app_intel/the-user-demographics-of-reddit-the-official-app-7e2e18b1e0e1](https://medium.com/$@$sm_app_intel/the-user-demographics-of-reddit-the-official-app-7e2e18b1e0e1)

⁶<https://www.pwc.com/gx/en/issues/workforce/hopes-and-fears-2022.html>

Fig. 3. Distribution across topics for four age groups (normalized).

posts with and without self-disclosed gender. Posts with self-disclosed gender received a mean of 12.82 comments (median = 6), compared to 14.36 comments (median = 7) for posts without gender disclosure. Similarly, the mean score for self-disclosed posts was 2.82 (median = 2.15), compared to 4.42 (median = 3.18) for non-disclosed posts. Although non-disclosed posts exhibit slightly higher engagement on average, the differences are modest, and medians are comparable, suggesting no substantial behavioral divergence between the two subsets. Topic distribution, approximated through subreddit participation, also indicates substantial overlap. A total of 350 subreddits were common to both groups, while only 13 subreddits appeared exclusively in posts containing self-disclosed gender. In contrast, 138 subreddits were unique to the non-disclosure group; these were predominantly professional, technical, and specialized-domain communities. This pattern likely reflects the lower prevalence of personal self-disclosure in highly technical forums rather than systematic differences in user populations.

A similar pattern emerges for age. Posts with self-disclosed age received a mean of 14.56 comments (median = 7), compared to 20.98 comments (median = 8) for posts where age was not disclosed. However, score patterns show the opposite trend: age-disclosed posts had higher mean scores (4.19; median = 2.88) than posts without age disclosure (mean = 2.91; median = 2.14). These mixed differences suggest variation in interaction style rather than systematic engagement bias. Subreddit coverage for age disclosure further indicates broad representativeness. Posts with age disclosure appeared across 474 subreddits, compared to 293 subreddits for posts without age information. Among these, 184 subreddits were unique to the age-disclosed group, whereas only 8 subreddits were exclusive to the non-disclosure group. This asymmetry suggests that age disclosure occurs across a wider range of communities, including both technical and non-technical spaces.

These comparisons indicate that posts containing demographic disclosures do not exhibit markedly different behavioral patterns from posts without such disclosures. Engagement metrics (comments and scores) are of similar magnitude across groups, median values are closely aligned, and subreddit participation shows substantial overlap. Observed differences, such as slightly higher comment counts in non-disclosed posts or broader subreddit coverage among age-disclosed posts, likely reflect contextual norms of discussion rather than systematic differences in the underlying population. Importantly, demographic disclosures appear across a wide range of communities rather than being concentrated within a small subset of forums. At the same time, the lower prevalence of disclosure in highly technical subreddits suggests that norms of professionalism or topic focus may discourage personal self-disclosure in those spaces.

Because demographic attributes in this dataset are inferred only when explicitly stated, they should be interpreted as properties of individual posts rather than stable characteristics of users. The available evidence suggests that posts with demographic disclosures are not a behaviorally

Table 8. Top 30 Salient Keywords as per Distinctness Scores [45]

Women Workers				Men Workers			
Keyword	Score	Keyword	Score	Keyword	Score	Keyword	Score
total-code	1.27	mother	0.73	cyber-security	-1.06	second-bachelor	-0.78

anomalous subset of the corpus and therefore are unlikely to introduce substantial bias in analyses conditioned on disclosure. However, as with all voluntary self-disclosure data, the sample may underrepresent contexts in which users are less inclined to share personal information. We acknowledge this limitation and treat demographic signals as context-dependent indicators rather than definitive user attributes.

5.2 RQ2.a: Language Differences across Gender and Age Groups

To characterize language differences in labor market content across different demographic groups, we apply an unsupervised language modeling technique, namely, the **Sparse Additive Generative Model (SAGE)** [45]. This technique retrieves the salient keywords in a given set of documents by measuring log-frequencies to distinguish between the lexical distribution of the document of our interest (i.e., posts written by women workers⁷) compared to a baseline document (the entire corpus) [45]. We refer to these log-frequencies as the “*distinctness score*”. This technique has been widely used as an effective approach among researchers who have studied lexical differences in social media, such as X [46, 147, 152], and Reddit [146, 157, 186]. We applied SAGE to the extracted phrases using the RAKE model (introduced in Section 4.3) to retrieve distinct phrases between the content posted by different gender and age groups.

5.2.1 Language Differences by Gender. Table 8 represents the results of our analysis to distinguish the unique phrases used by workers discussing labor market topics. The scores reported in this figure indicate the degree of word uniqueness in each gender group. A positive score shows greater distinctness of phrases among women, and a negative score shows greater distinctness of phrases among men workers. By examining the results in Table 8, we identify the following findings:

Women’s focus on social connections. As illustrated in Table 8, distinct keywords used by women were dominated by social references, such as women references (e.g., “female”, “woman”, “lady”, “girl”) and family/interpersonal relationships references (e.g., “daughter”, “mom”, “sister”). Unlike women workers and aligned with the prior work which studied job satisfaction across demographics

⁷We embrace “women” as an adjective in this work to reach a broader meaning that places gender over biological sex.

[147], we found that the salient keywords for men were centered around occupations and job titles (project management, years of experience, software engineer, start working), education (“bachelor’s degree”, “master degree”, “Ph.D.”, “MBA”), and growth (“online course”, “double major”).

We observed that while the main purpose of Reddit posts generated by both women and men information workers was around obtaining answer/support to a variety of inquiries related to recruitment and learning, many women provided more detailed information about their background, family, and motivation behind the expressed question compared to men. For example, several workers used phrases that referred to social and interpersonal relationships to express the influence that those relationships had on the situation they described in their posts. This influence was expressed as fear of failing others by unsuccessful results, having the support of others to make the right decisions, or concerns around the outcome of particular actions on others. For example, one of the women workers who wanted to start a freelancing job wrote: *“I have a full-time job but I am feeling like a robot trying to finish my to-do list every day and I feel a little depressed. My husband travels every two weeks [...] My son spends most of his summer in camps [...] I have a mom who lives abroad [...] I like to spend more time with my family [...] Is freelancing a good option for me?”*. As portrayed in the above example, the workers presented their situation and priorities (references to the mom, child, and spouse) to seek support from the community on a job change. Our findings are consistent with prior research conducted by [117] who reported that women were more likely to form their conversations around people and their internal processes as opposed to men who prioritize their discussions around their occupations and external events.

Women express more psychological words. In addition to the differences in how women workers form their conversations and priorities compared to men workers, we observed a noticeable difference in the use of psychological words. By psychological, we refer to words that express emotional and cognitive experiences. Overall, our results reported in Table 8, revealed that women are, on average, more expressive of their emotions and well-being compared to men. For example, frequently used salient words by women workers were “pissed”, “cry”, “therapist”, “ADHD”, “angry”, and “ashamed”, while none of the top 30 distinct words expressed by men workers were around well-being. This finding is consistent with prior research that found when disclosing information, women use words to describe their emotional states, especially negative emotions, more than men [14, 167, 171]. We explore these differences in the expressed emotions and well-being across gender with statistical models in the next section.

5.2.2 Language Differences by Age. In Table 9, we present the distinct phrases used by workers in different age groups discussing the labor market topics. The scores reported in this Table indicate the degree of word uniqueness in each age group. We yield the following observations:

Career advice for younger workers. We find that among all workers, younger people rely more on online communities to seek career advice. We noticed that individuals under the age of 25 requested career advice by using keywords such as “career choice”, “career guidance”, and “decent money”, which could suggest that these young people rely on online communities to shape their future decisions or paths. For example, a user posting *“I am a new college graduate and I am desperately trying to get a job closer to my family. Although I have done one decent internship, my resume is on the weaker side. I have 2 questions: (1) how to deal with negative emotions after rejections, (2) how to set myself apart from more experienced candidates (like online certifications, YouTube lectures, etc.)?”*

Career switch for older workers. We found that some of the unique words used by workers above 30 are around career change, such as “change career”, “career change”, and “career switch”. For example, one worker mentioned a plateau in their career, which motivated them to further their learning, which would eventually lead to a job change to one that would be more challenging and have room

Table 9. Top 30 Salient Keywords as per Distinctness Scores [45]

Under 18				18-25

Bar lengths indicate the magnitude of scores; The **positive scores** show greater distinctness of phrases among workers in the specified age range.

for growth: “I have an MBA and no technical background with several years of experience in analytics in various tech companies. We can assume there are few to no learning opportunities at my current job (outside of learning on my own). We can also assume there is no room to move up in my current company. At this point in my career, would it be worth it to get some sort of statistics/analytics Bootcamp credential?”. In addition to career change, this age group had references to financial commitments and long-term goals through keywords such as “mortgage”, “retirement”, and “pension”. Overall, our findings could suggest that while workers in other age groups try to enter the workforce and upgrade their skills or establish themselves more in their current occupations, older workers’ priority is to change their careers or fields to break a plateau, gain financial advantage, or find jobs that are more fulfilling than their current ones. Our findings align well with earlier studies on behavioral patterns of older job seekers [97, 184]. For instance, [97] reports that job-seeking motivations for older adults could be categorized based on factors addressing their income, among others. This finding can be important for employers to understand the needs of their employees better and work on solutions to help the workforce with growth and learning plans to prevent

attrition, increase their productivity, and find fulfillment while employed. We discuss these findings in more detail in Section 6.

5.3 RQ2.b: Psycholinguistic Differences across Gender and Age Groups

We next discuss results related to psycholinguistic differences disclosed in information workers' content across different aspects of the labor market based on workers' gender and age groups. To address this, influenced by several earlier works that utilized a lexicon to identify the psycholinguistic characteristics of social media language [144, 158, 186], we used the well-validated Linguistic Inquiry and Word Count 2022 (LIWC-22) lexicon [17] to understand how information workers express their psychological well-being. The LIWC lexicon has 50 categories that include words from the interpersonal focus, lexical density and awareness, personal and social concerns, cognitive processes, affect, health and behavioral states, motives, perception, and temporal reference categories representing a range of psychological attributes. Prior research has emphasized the importance of lexical analysis for understanding the psychological well-being and processes of individuals [141, 144]. For example, it has been shown that variation in using articles and pronouns can reveal critical information on people's reactions to complex psychological stimuli [32, 138].

After extracting psycholinguistic characteristics of workers' labor market content, we statistically test the normality of our data by performing the Shapiro–Wilk test on each category. A p-value of less than 0.05 was found by the Shapiro–Wilk test on each of the psycholinguistic characteristics of our four labor market topics (Skill Development, Job Applications/Job Search, Education, and Employment/Job Concerns), indicating that our data on the labor market is not normally distributed. To determine whether there are statistically significant differences between two or more groups that are not normally distributed, we use the Kruskal–Wallis H-test to analyze the psychological well-being of information workers. Then, we measured the effect size using Cohen's *d* to estimate the differences between the groups' means. Note that Cohen's *d* was only measured for significant psychological categories based on the Kruskal–Wallis H-test.

5.3.1 Psycholinguistic Differences by Gender. Table 10 represents the distinctive psycholinguistic characteristics across the labor market topics and gender groups. By examining the results in Table 10, we offer the following observations:

Affective and health attributes. As discussed in Section 5.2.1, we found a greater prevalence of keywords related to emotional well-being in content posted by women workers. Similarly, our analysis of workers' psycholinguistic attributes, illustrated in Table 10, revealed that negative affective categories, such as “negative tone” were more prevalent in content posted by women workers. Specifically, we found a greater usage of negative attributes, such as “anxiety”, “anger”, and “sadness” in women workers' content when disclosing information about the Education and Skill Development topics, and a higher prevalence of positive tone among men workers when discussing Job Applications/Job Search topic. However, we found no significant differences between affective attributes used by women and men who discussed Employment/Job Concerns. Our finding on the difference between disclosure of negative affective attributes is aligned with [167], which showed women are more expressive of their negative emotions compared to men. Among health attributes, women are more expressive about health and behavioral states, e.g., “*I dropped out of college due to depression and drug addiction, but now I am trying to resume my education.*” While these categories have negative implications, prior research suggests that disclosing information regarding emotions and health can improve psychological well-being and help to cope with hardship [123].

Motivations, personal and social concerns. Among personal and social attributes, we find that men workers have a higher prevalence of attributes related to prosocial behavior (tendency to help or

care about others), communication (e.g., talk, explain, or ask), and politeness (e.g., please or thanks), e.g., “Hey, I have my interview soon. They’ll ask me about scripting, and I told them I am going to do it in Python. Can you help me to prepare for it? Thank you so much!”. Also, we observed that men had greater usage of keywords around their careers, such as “achievement”, “technology”, and “work”, followed by high usage of keywords related to curiosity as their motives; e.g., “I want to be a great programmer, so I’ve done online learning for python and JavaScript. My plan in life would be software engineering, and I want to learn more!”. Unlike men workers, we find a greater prevalence

of keywords about family, friends, and home in the content posted by women. For example, *I am interested in Architecture and Animation, but my parents forced me to take computer science because my mom thinks I am bad at drawing and my stepdad is against Animation*. This finding is aligned with our earlier observation in Section 5.2.1, where we reported that women workers have a higher tendency to focus on social connections while men are more focused on career growth.

5.3.2 Psycholinguistic Differences by Age. We identified distinctive psycholinguistic characteristics across the labor market topics and age groups by examining the psycholinguistic attributes indicated in workers' Reddit posts. We found that although there are significant differences across genders when discussing **Employment/Job Concerns**, there is no significant difference in the psycholinguistic attributes of workers in different age groups. This section reports our findings on labor market topics with a statistically significant difference in the expressed keywords across age groups. We also report our findings in Table 12, Table 13, and Table 11.

Affective and cognitive attributes. Among cognitive categories, we observe that workers under the age of 18 show the highest prevalence of words related to discrepancy (Table 12, Table 13, and Table 11) and tentativeness (Table 12 and Table 11), which represent a person's uncertainty and insecurity over the circumstance [146]. For instance, *"I'm 16 and I think I might be getting my first job!"* or *"I'm a 15 yo sophomore. I was just wondering what I should actively be doing if I want a career in mechanical engineering"*. Among the affective categories, we find that workers under the age of 18 revealed the highest usage of positive tone in **Skill Development** (Table 13), which might suggest that learning for workers under 18 is an overall positive experience. In contrast, workers between the ages of 18 and 25 used the most keywords around negative tone, anxiety, and anger in **Education** (Table 12). This might be associated with the majority of individuals between the ages of 18 and 25 being college students, who disclose negative emotions about their campus life or trying difficulties in trying to get some professional work experience, e.g., *"College grad, lost, frustrated [...] I'm just lost as to what I should be doing/what I'm doing wrong. I've been applying*

Following Bonferroni correction, statistical significance is reported as follows: *** $p < .001$, ** $.001 < p < .01$, * $.01 < p < .05$.

nonstop for a while now to all kinds of jobs with no luck.” Our observations about the negativity expressed by college-age workers can also be explained by the findings of [61], which show that the expression of negative emotions by college students is strongly correlated with positive support received from their peers, e.g., their roommates.

Temporal references, personal, and social concerns. Among personal and social concerns, we find that workers above the age of 25 use the most number of terms around “achievement”, “work”, and “money” when discussing **Education** (Table 12), while prevalent keywords among workers under the age of 25 were around “leisure” with a focus on the present time. This finding could mean that as workers become older, their priorities for pursuing education or getting a formal degree shift toward following a passion, becoming more successful, or finding a better career with more income, e.g., *“I am 32 yrs. and have been a nurse for a few years. I am considering going back to school for Computer Engineering because I think it’s fascinating and want to learn how to create and develop hospital EMRs, since I have so many ideas working with different systems.”* When discussing **Skill Development** (Table 13), we observe a higher focus on the present time in workers’ content under the age of 25 and a higher focus on the past time in workers’ content above the age of 25. We also found a distinct usage of keywords in revealed personal and social concerns among different age groups. For example, we observed the highest prevalence of keywords related to “family” and “communication” for workers under the age of 18, “achievement”, “work”, and “home” for workers between the ages of 25 and 30, and “power”, “interpersonal conflicts”, and “politics” for workers above the age of 30. The difference in the use of keywords in the personal and social categories could be associated with the fact that, while in the rapidly changing labor market, workers are demanded to be lifelong learners who continuously update their skills [105, 106], the learning process takes different shapes depending on the age group.

Linguistic style attributes. We find a significant difference between pronoun usage across age groups, especially among the workers under the age of 25, which is an indication of different social attentions [146]. For example, we observed a high prevalence of first-person singular pronouns (e.g., me, my, myself) in workers’ content under the age of 25 who discussed **Education** and **Skill Development** (Table 12 and Table 13), which can indicate a higher focus on personal experiences and self-reflection [124]. For example, *“I started my career in graphic design last year, but I am concerned about my choice. This job makes me feel overwhelmed, and I don’t get motivated by it. Should I continue with this career?”* where the workers disclose their challenges with their career. However, we only found a high usage of keywords related to first-person singular pronouns in the workers’ content aged between 18 and 25 who discussed **Job Application/Job Search** (Table 11). For instance: *“I have been out of college for 2 years, but I can’t even get an internship. I have done a few projects to build my portfolio, but I still think I am unqualified [...]”*. Prior studies show that understanding people’s social attention is an important factor in effective social interactions [34], which can be an essential component when addressing workers’ needs.

6 Discussion

Rapid advancements in digital technologies, alongside global disruptions such as the COVID-19 pandemic, have reshaped labor-market structures and workers’ experiences of employment [49, 58, 116, 162]. Within Social Computing research, there has been sustained interest in understanding how these shifts impact occupations, employment, and workers [99, 113, 174, 179]. As highlighted earlier in this article, prior work has largely relied on qualitative studies, surveys, and interviews to examine worker well-being and occupational change. In contrast, our work leverages large-scale social media data to examine how workers collectively disclose, interpret, and socially negotiate labor-market challenges in online communities.

Using Reddit as a social environment rather than merely a data source, we analyze how information workers discuss education, learning, job search, and employment concerns, and how these disclosures vary across gender and age groups. Our findings highlight systematic differences in patterns of self-disclosure, emotional expression, and topical focus, revealing how demographic characteristics intersect with social roles in shaping online labor-market discourse. In the following sections, we situate these findings within Social Computing research and discuss their implications for understanding online communities as infrastructures for collective well-being and peer support.

6.1 Online Communities as a Lens to Understand Information Workers' Needs

In the fast-evolving labor market, social media platforms have become critical spaces where workers collectively make sense of occupational change and uncertainty. Prior Social Computing research has shown that rapid shifts in skills and job requirements lead people to rely heavily on their personal networks and online communities for skill and professional development [89, 90, 108]. Consistent with this work, our findings show that skill development emerges as a dominant and recurring theme across labor-market discussions, highlighting its central role in collective sensemaking among information workers.

Importantly, learning and skill development were not discussed solely as instrumental goals but were frequently embedded within narratives of anxiety, frustration, and uncertainty. Workers turned to online communities to ask peers what skills to acquire, where to learn them, and how to remain relevant in the knowledge economy. These interactions reflect recognizable social mechanisms: advice-seeking, experience sharing, reassurance, and the normalization of career-related distress. In this sense, Reddit functions as a peer-based support environment, where informational guidance is intertwined with emotional validation. Our qualitative examples further demonstrate how perceived lack of learning opportunities can lead to dissatisfaction and discussions of turnover, underscoring the role of online communities in normalizing and articulating career-related distress.

Building on literature that highlights the value of user-generated content for understanding labor-market trends, hiring practices, and talent acquisition [80, 86, 105, 106], we extend this perspective by emphasizing the relational and interactive dimensions of such discourse. Rather than treating social media merely as a predictive signal of market shifts, we conceptualize it as a site where workers publicly perform vulnerability, seek solidarity, and negotiate shared understandings of success, failure, and resilience in the knowledge economy.

Beyond reflecting workers' voices, our results further demonstrate how online communities make psychological well-being socially visible. We showed that when workers discuss topics such as learning and education, they express the most negative affect, i.e., anger, anxiety, and sadness. These emotional expressions are not isolated signals but are embedded in interactional contexts shaped by platform affordances. Social media enables users to form diverse relationships, disclose self-initiated content, and express their emotions as they experience them. For instance, on social media sites, such as X and Reddit, individuals with differing ages, genders, ethnic origins, and social power create virtual communities based on weak ties to engage with one another [187]. Because of these weak relationships, users can openly exchange their experiences and express their emotions and concerns regarding a variety of topics, such as unemployment, which they might not freely disclose with their intimate relationships [57].

Moreover, many individuals, particularly young people, rely on social media to articulate psychological distress and seek health-related information due to the possibility of anonymity and asynchronous interaction [127]. From a Social Computing perspective, these affordances help explain why Reddit serves not only as a discussion forum but as a collective well-being space, where patterns of disclosure accumulate into shared narratives about work and uncertainty. In this

way, Reddit operates as a form of collective sensing for labor-market well-being, complementing traditional surveys and interviews [104, 147].

At the same time, the use of social media data raises important ethical tensions. While such data are inexpensive, unobtrusive, and near real-time [147]. We also recognize that Reddit users might view this type of data collection to be a form of surveillance and choose to circumvent the technology by moving to private forums, as Chinese citizens did after the implementation of the XueXi QiangGuo government platform [100]. Thus, informing affected members and communities of the analysis conducted and incorporating an opt-in/opt-out consent mechanism for individuals or perhaps forums is warranted before risking the invasion of user privacy.

6.2 Online Professional Communities as Support Infrastructures

Our findings also have implications for the design of support systems informed by Social Computing research [40, 105, 115, 137]. With the rise of a skilled labor shortage in **Science, Technology, Engineering, and Mathematics (STEM)** fields [48], many organizations have prioritized enhancing employee experience and retention. Previous studies argue that factors such as providing growth opportunities, engaging with meaningful work, and ensuring work-life balance can prevent attrition more than high compensation for many information workers [20]. As such, more institutions have invested in employee training and upskilling to prevent employee attrition, improve productivity, and keep workers up-to-date [109]. Although these organizational strategies are critical, our findings suggest that workers' needs are deeply shaped by life stage, gender, and social context, as reflected in their online disclosures.

Viewed through a Social Computing lens, Reddit and similar platforms function as informal support infrastructures where workers articulate challenges, compare experiences, and seek validation beyond formal organizational channels. Our findings demonstrate that workers' concerns vary systematically across age and gender, and that these differences are reflected not only in the topics discussed but also in the language used to express them. For example, workers aged 30 or older frequently discussed career transitions and long-term financial stability, including retirement and pension planning, suggesting that online communities serve as spaces for deliberative reflection on mid- and late-career identity. In contrast, younger workers focused more heavily on entering the job market and establishing career trajectories, often framing these concerns through uncertainty and exploration. These differences reflect life-stage-specific social roles and expectations that shape how workers participate in online discussions and what forms of support they seek.

Similarly, we observed gendered differences in self-disclosure patterns. Women more often articulated concerns tied to social relationships, belonging, and psychological well-being, whereas men emphasized career advancement and instrumental outcomes. Rather than interpreting these disparities solely as individual preferences, they represent reflections of broader social norms around professional identity and emotional expression. In this way, online discourse reveals how gendered expectations shape participation and help-seeking behavior within professional communities.

These findings extend beyond organizational design and define online communities in complementing, and sometimes compensating for, formal workplace support structures. Prior work has demonstrated the importance of social support in reducing anxiety and improving well-being [151], as well as the value of collective representation in advocating for workers' rights [53]. Our results suggest that online communities similarly provide spaces where workers collectively express dissatisfaction, normalize shared struggles, and exchange coping strategies. Such peer-based interactions provide opportunities to design interventions, both within online platforms and organizational contexts, that align with existing community norms and modes of disclosure, rather than imposing one-size-fits-all solutions [101].

While organizations may draw on these insights to design more responsive support programs, i.e., targeted reskilling initiatives or career mobility pathways [43, 81, 94, 126, 164], the central contribution of this work lies in illuminating how online communities surface and organize workers' concerns at scale. Understanding these dynamics is critical for Social Computing scholars interested in how community discourse shapes well-being in the evolving world of work.

6.3 Implications of Automatic Gender Retrieval

In this study, we included gender to highlight that interpersonal differences between individuals should be considered when studying the needs and well-being of workers to design more effective support systems. Yet gender identity is a social construct and people's gender experiences are constantly evolving [156]. However, our extracted data from Reddit did not contain a dedicated field for gender expressed by the users themselves. One of the common procedures for including self-identified genders in research is through user input, which can be obtained through surveys and interviews [153]. Nevertheless, applying those approaches is not feasible when researching large-scale social media data, i.e., online social networks. With technological advancements and the widespread use of NLP and machine learning, researchers have increasingly focused on detecting an individual's gender from social data [4, 16, 169], a similar approach that we inherited in this work. While this development offers potential for a variety of applications, it also raises significant implications and ethical concerns that merit a closer examination.

One of the important concerns with automatic gender detection algorithms is the potential for algorithmic bias and stereotyping [96, 155]. Algorithms trained on existing text data might inadvertently reinforce gender stereotypes, as they learn from historical language usage patterns that reflect societal biases [159]. This can lead to unfair categorizations, discrimination, or exclusion of individuals who do not conform to traditional gender norms. To identify the existence of such biases in our gender detection algorithm, we conducted a qualitative error analysis technique on 1% (241) of the posts where the author explicitly mentioned their gender, i.e., "I am a female" or "I am a man". By comparing the text and the automatic gender labels assigned by the algorithm we witnessed interesting cases. For example, we noticed that in posts where the author self-identified themselves as a female trans person, the algorithm correctly categorized them in the "Female" group. For example:

- Is this job feasible for a trans person (trans female, male to female)?
- I am 31, a trans woman from South America.
- I am a 32-year-old, queer, middle eastern woman seeking a mentor.

In other cases where the gender was falsely identified as a "Female" or "Male", we noticed that the posts contained many "male" or "female" references or were describing experiences of a "female" or "male" subject. For example, one of the authors dedicated their post to the 22 most successful male workers in the industry and a few more lines about their biography. Although the mentioned example did not contain any self-identified gender of the authors, the algorithm labeled the post as "Male", potentially due to the high usage of "male" references. In another post, a worker described how they are overworked in their current position and mentioned that they are looking for a job to be able to spend more time with their wife. In this example, although the post was missing the self-expressed gender of the author, this post was categorized into the "Male" group, potentially because of the existence of the word "wife" in the text. While the correct identification of trans-gender authors by the algorithm was heartwarming and the overall performance of the model, as reported in Table 7, was satisfactory compared to previous literature, we acknowledge the potential harm of analysis on falsely classified data because of the societal stereotypes.

Moreover, consideration of gender as a binary construct oversimplifies the rich spectrum of gender identities that exist and can result in a lack of inclusivity, alienating individuals who identify as non-binary, genderqueer, or trans, thus failing to recognize their authentic identities [19]. Also, in many contexts, a binary view of gender reinforces stereotypical gender roles and expectations, limiting individual freedom, expression, and opportunities. As society becomes more aware of the limitations and injustices tied to a binary understanding of gender, there is a growing movement to recognize and respect a wider spectrum of gender identities [180]. However, there is still a wide gap between the research community's efforts to acknowledge nuances in gender identities and the existing algorithmic approaches and guidelines that allow social computing researchers to identify gender. We recognize that significant further work must be done to accommodate a more comprehensive and inclusive range of gender identities [98] and to prevent unwanted harm to marginalized populations. In the context of our work, one possible way to include non-binary individuals would be conducting research on non-binary advocacy groups, such as "r/NonBinary" subreddit on the Reddit platform. These individuals and groups frequently exchange information, resources, and personal stories about non-binary experiences. Another way to include non-binary individuals in social media research is obtaining the pronouns and terminologies being used by non-binary groups, such as the informal term "enby", which is frequently used to describe people who identify as non-binary genders [79]. While such efforts require further expertise, for the current study, we reluctantly categorized users into binary groups based on self-identification of women or men. We discuss the ethical considerations of our decision. [154] argues that "If gender must be used, consider the context of its application". Women have reported experiencing gender discrimination in the U.S. labor force and have had higher prevalence rates of gender discrimination in male-dominated fields [24]. We felt that, despite not having adequate means of categorizing non-women or men identities, understanding whether and how these inequities manifest themselves in online forums is an essential initial investigation.

6.4 Demographic Representation and Participation Bias

While online social media data enables the large-scale and timely study of labor market discourse, previous research has emphasized *selection and participation bias* as a potential problem in social media studies [147]. Selection bias arises when platform populations systematically over- or under-represent individuals along demographic dimensions such as gender, age, education, income, and geographic location [148]. Participation bias further compounds this issue, as individuals from certain demographic groups are not only more likely to be present on a platform, but also more likely to actively contribute content, while others remain comparatively silent [125]. Together, these mechanisms shape whose experiences are rendered visible in online discourse.

Reddit exemplifies these representational dynamics. Prior analyses of Reddit's user base document a pronounced skew toward younger, male, and digitally proficient users, with higher participation from English-speaking, Global North countries. Existing demographic analyses report that approximately two-thirds of Reddit users identify as male, and that the majority fall between the ages of 18 and 29, with disproportionate representation from the United States, Canada, the United Kingdom, and Australia.⁸ Beyond platform demographics, Social Computing research has shown that social media platforms tend to disproportionately attract individuals with higher levels of digital literacy, technology self-efficacy, and educational attainment—attributes that are unevenly distributed across populations and correlated with socioeconomic status [2, 103, 133]. As a result, the voices most visible in social media datasets often reflect not only platform design but also inequalities in access, confidence, and capacity for sustained online participation.

⁸<https://www.alphr.com/demographics-reddit/>

Participation inequality further amplifies these skews. Previous work demonstrates that content production in online communities is highly unequal and strongly associated with socioeconomic factors such as education and income [102]. Consequently, demographic biases present at the platform level are often magnified in datasets derived from posts and comments, as groups who contribute less frequently, such as women, older individuals, and users from non-Western contexts, are rendered statistically marginal even when they are present on the platform. The composition of our dataset reflects these well-documented dynamics: users contributing IT-related content predominantly belong to demographic groups that are already overrepresented both within Reddit and within the IT workforce itself.

Importantly, these representational patterns mirror long-standing demographic inequalities in high-technology labor markets. Despite sustained efforts by governments, academic institutions, and nonprofit organizations to improve diversity in **science, technology, engineering, mathematics, and medicine (STEMM)**, underrepresentation remains persistent [67]. Recent reports from the U.S. Equal Employment Opportunity Commission indicate that women, Black and Hispanic workers, and older individuals remain substantially underrepresented in high-tech occupations.⁹ For example, while women constitute approximately half of the U.S. workforce, they hold fewer than one-fifth of high-tech positions. Similarly, high-tech employment is disproportionately concentrated among workers aged 25–39, and STEM occupations remain overwhelmingly dominated by white workers [54]. Educational stratification further contributes to these patterns, as STEM and IT roles are significantly more likely than other occupations to require a bachelor's degree or higher [50, 54]. These workforce inequalities shape not only who works in IT, but also who participates in online discussions about IT labor markets.

From a Social Computing perspective, these demographic and participation biases should not be interpreted solely as limitations but as sociotechnical phenomena that reveal how online platforms mediate visibility, voice, and collective sensemaking. Our findings thus reflect how labor market challenges and well-being concerns are articulated and negotiated primarily within a dominant subgroup of the IT/Reddit ecosystem. While this necessitates caution in generalizing results to underrepresented populations, it also offers insight into whose experiences become normative in online labor market discourse, and how platform-specific participation structures shape collective representations of work and well-being. Recognizing these representational dynamics underscores the importance of future research that combines social media analysis with complementary data sources and methodological approaches, including targeted sampling, mixed methods, and community-engaged research designs. Such efforts are essential for surfacing the perspectives of marginalized groups and for developing a more inclusive understanding of labor market challenges and collective well-being in the knowledge economy.

6.5 Dataset Scope and Generalizability

The dataset analyzed in this study spans Reddit posts published between January 2015 and August 2019. This period was selected to capture labor market discourse during a relatively stable pre-pandemic phase of the global economy. Before early 2020, labor market conditions in many regions were characterized by steady employment trends, gradual technological transformation, and incremental shifts in workplace practices rather than abrupt systemic disruptions [73]. By focusing on this window, the analysis aims to examine baseline patterns of demographic participation and topic engagement in online labor-related discussions under non-crisis conditions.

To further assess whether the identified topical structure is specific to the 2015–2019 window or reflects more persistent patterns in IT-related labor discourse, we applied the same inductive coding

⁹<https://www.eeoc.gov/newsroom/eeoc-research-finds-unequal-opportunity-high-tech-sector-and-workforce>

procedure to an additional temporal slice spanning March 2020 to December 2021, as described in Section 4.1 and reported in Appendix B. Using three independent coders, we reconstructed the codebook for this later period and compared it to the original taxonomy derived from the pre-pandemic data. We observed substantial continuity across periods, with 83.5% of the identified codes overlapping with the original codebook. The dominant themes, namely, Skill Development, Job Applications/Job Search, Education, and Employment/Job Concerns, remained central to the discourse. While certain context-specific concerns emerged in the later period, the core structure of labor market discussions among information workers persisted. These findings suggest that the 2015–2019 dataset captures stable thematic foundations of IT-related labor discourse rather than a transient interval.

Furthermore, the onset of the COVID-19 pandemic in early 2020 introduced a structural break in labor market dynamics. Rapid expansion of remote work, widespread layoffs, emergency public policy interventions, and heightened uncertainty substantially altered both employment conditions and public discourse surrounding work [120]. These changes likely affected not only the salience of particular labor market topics but also the ways individuals publicly articulated work-related concerns. Restricting data to the pre-2020 period reduces the confounding influence of these extraordinary events and enables the identification of structural patterns less driven by short-term crisis responses.

Importantly, the objective of this study is not to characterize all contemporary labor market discourse, but rather to examine demographic participation patterns within a defined historical context. The findings, therefore, reflect communicative behaviors and topic distributions in the pre-pandemic labor market. While specific themes, such as remote work or pandemic-related job displacement, became more prominent after 2020 [15], the demographic asymmetries and disclosure practices identified here are likely rooted in broader social and platform-level norms rather than solely in transient external shocks.

At the same time, the temporal scope necessarily limits the generalizability of the findings to post-2020 labor market conditions. Crisis environments may amplify or attenuate certain participation patterns, alter norms of self-disclosure, or reshape the composition of online communities. Extending this analysis to subsequent periods represents an important direction for future research, particularly to examine whether demographic-topic associations remain stable under large-scale economic disruption [25]. Accordingly, the results should be interpreted as reflecting pre-pandemic labor discourse on Reddit. They provide a baseline against which post-2020 transformations in online labor conversations may be meaningfully compared.

Beyond capturing a pre-pandemic snapshot of online labor discourse, the dataset also provides a useful historical baseline for examining how discussions about work, skills, and well-being evolve as technological paradigms reshape the workplace. The analyzed posts predate the widespread integration of generative AI systems and AI-assisted workflows that have begun to influence many knowledge-intensive professions. As AI increasingly mediates how information workers perform tasks, develop expertise, and navigate career pathways, online communities are likely to remain important spaces where individuals collectively interpret and negotiate these transformations. The thematic structures and demographic participation patterns identified in this study therefore establish a reference point for future longitudinal research examining how discourse around work, automation, and professional identity shifts as AI becomes more deeply embedded in daily work. In this sense, the dataset can serve as a pre-AI baseline for understanding how technological change reshapes conversations about skills, employment, and well-being in online labor communities.

Taken together, the dataset and findings presented in this study establish a pre-pandemic, pre-AI baseline of online labor discourse among information workers, enabling future Social Computing research to systematically examine how emerging technological and economic transformations reshape conversations about work, skills, and well-being in online communities.

6.6 Ethical Considerations

In this data-driven age, the use of open data in research has become increasingly prevalent. Publicly accessible data sources, including social media posts and open-access scientific databases, provide researchers with a wealth of information for investigations across various disciplines [119]. While it is clear that having access to such data has broadened research possibilities, scholars argue that the blurred line between public and private data can lead to potential harm and negative implications for individuals [129]. For instance, although some online social platforms, such as X, warn users about the usage of public data by researchers under the Privacy Policy section, some online research subjects are unaware that their data is being used by academics [52]. Also, usually, online users do not have any control over the type of data that is collected for research purposes [172]. Additionally, users may have written identifiable private information in public data as a means of seeking social support during a crisis; hence, failing to restrict the revealing of people's identities in research may endanger users [163].

To this end, while this study primarily utilizes public social media data to help organizations better understand the information workers' challenges and needs, especially those who belong to marginalized groups, such as women, we recognize that some users may consider social media analytics to constitute surveillance. To limit the unwanted harm to the users, we made sure to anonymize any quotations that could trace the content to the users. Also, we did not keep any usernames or names of the users in our dataset to protect the privacy of the users. However, we acknowledge that while individuals might decide to share information about their career challenges or overall well-being in a workplace in a public forum, they might be reluctant to provide their employers with their online social content [147]. One possible way to overcome this challenge is to engage with the social platform under study, i.e., forums administrative, to inform users about the collection of their data and provide them with an opportunity to opt out of the research.

6.7 Limitations and Future Directions

We acknowledge that our research is not without limitations. First, while online social media data can assist in capturing and analyzing timely labor market issues at a large scale, previous research has emphasized *selection bias* as a potential problem in social media studies [147]. Also, our dataset may likely lean toward the viewpoints of those who reside in the Global North and belong to a certain ethnic group. Therefore, we note that the self-disclosed content in our Reddit data may not necessarily be representative of a diverse labor market. Moreover, we only analyzed English Reddit data, and hence our work is not representative of the rich lived experiences of those information workers who communicate in languages other than English. To address these limitations, further studies are required to assess information workers' concerns and well-being using data from various social media platforms to paint a more complete picture.

We also acknowledge that more factors beyond gender and age can influence the challenges that workers experience in the job market. For example, socioeconomic status, education level, marital status, family size, personality traits, and lifestyles such as alcohol consumption, smoking, exercising, or prior health issues, and disabilities, among others, can also have an impact on the reported challenges and worker well-being [38, 39, 41, 107]. Despite limitations, we hope that our work inspires future research to examine the societal factors that impact the experience and emotions of information workers across broader demographic groups.

7 Concluding Remarks

This article leverages social media data to identify the challenges and the psychological well-being of information workers in the evolving labor market. Using machine learning techniques, we identified Skill Development, Job Applications/Job Search, Employment/Job Complaints, and Education as the most discussed topics among information workers. We also looked at linguistic variations

among different genders and age groups in online communities. Concerning gender, we found that, on average, women workers report more psychological issues and negative affect than men. While men express more concerns about their jobs, job titles, education, and progress, women are more likely to express concerns about their health, families, and interpersonal connections. For age, we found that younger workers rely on online communities to seek career advice, while older workers disclose/require information about career changes. We also found high uncertainty in all labor market topics and a positive affect regarding learning topics among youth workers (under 18) and a higher negative affect among workers between the ages of 18 and 25 who discussed the Education topic. This article is among the first to use social media data, statistical methods, and machine learning techniques to shed light on information workers' challenges and the areas in which workers require the most support, and it advances our understanding of workers' well-being in the emerging labor market, considering their age and gender.

Appendices

A Data Collection Strategy

In this section, we discuss our data collection strategy and explain our choice to selectively curate posts explicitly referencing IT skills from various subreddits instead of opting for an all-encompassing approach by collecting all posts solely from a dedicated IT subreddit. First and foremost, opting to select all posts from a dedicated IT subreddit introduces a potential source of selection bias. This bias arises from the inherent differences in tone, language, and context across various subreddits [177]. Each subreddit develops its unique community norms, communication styles, and jargon, which can significantly affect the content shared within it. For example, in a study conducted by [122], the authors explored the commonalities and distinctions in content discussed by Reddit users across three mental health-related subreddits. Employing an unsupervised technique, namely K-means, the authors found that while a few themes like expressions of gratitude and positive emotions were shared among the subreddits, the majority of topics were unique to each subreddit. Therefore, by exclusively focusing on particular IT-dedicated subreddits, there is a risk of overlooking valuable insights and discussions occurring in other communities where IT skills are discussed in a context-specific manner. Thus, this selection approach risks favoring posts that align with the tone and language of the IT subreddit while excluding potentially relevant contributions from the broader Reddit community.

Furthermore, our quantitative analysis of the subreddit titles and their content showed that in addition to communities dedicated to particular skills, i.e., “r/Javascript”, “r/Programming”, and “r/PostgreSQL”, by applying our data collection approach explained in Section 3, we were also able to include a wider range of subreddits, such as “r/InformationTechnology”, and “r/Redditdev”, where more general IT-related topics were discussed. We analyzed all the posts that were posted within a 30-day period in our dataset for each subreddit and computed the frequency of the posts that contained one of our IT skills in their body or title. We found that while the majority of the posts in skill-related subreddits contained one of the IT skills in the posts, i.e., 64% in “r/CSS”, 75% in “r/SQL”, and 93% in “r/docker”, a noticeable portion of the posts in more general IT-related subreddits also contained at least one of our IT-skills. For example, 33% of the posts in “r/computerscience”, 30% in “r/ComputerEngineering”, and 29% in “r/TechInsightreports” mentioned one of our IT skills in them. This observation demonstrates that while by focusing on the posts based on a list of IT skills, we might overlook some of the issues that IT workers discuss without mentioning IT skill terms,

our data collection method was able to capture a more comprehensive and diverse range of relevant discussions that may not surface within the confines of a specialized IT-focused subreddit. This approach allows for a richer and more holistic understanding of how IT skills are employed and discussed across Reddit's vast and multifaceted landscape of communities.

B Codebook Validity (Extended Analysis with Additional Data)

To investigate whether IT workers' challenges remain the same or change over time, we obtained additional Reddit posts from Pushshift, posted between March 2020 and December 2021. Based on the additional data, we followed the same data pre-processing steps explained in Section 3 to prepare the collected data for further analysis. As a result, we collected an additional 459,156 unique posts in 516 subreddits, posted by 259,286 unique users. To identify the topics discussed in Reddit posts, as discussed in Section 4.1, we created a codebook by employing an inductive coding technique. To find the conceptual categories in the new data, we randomly sampled 1,000 Reddit posts out of 459,156 to develop the codebook. To avoid potential biases, we recruited and trained three coders familiar with labor market topics who were not involved in the original coding process to individually code each sample in the 1,000 posts. After an iterative process in which the three coders met regularly to form the conceptual categories, the coders verified the obtained codebook. We found that 83.5% of the identified codes were completely overlapping with the findings reported in the results in this article. The list of additional unique codes (remaining non-overlapping 17% of codes) and a detailed description of them can be found in Table 14. Please note that in Table 14, we only reported the new codes that the coders identified in the new data that were not mentioned in Table 3.

Table 14. Codebook of New Topics Derived From Reddit Posts Extracted Between March 2020 and December 2021 That Were Different from Those Observed Between January 2015 and August 2019

Topic	Definition
Community Appreciation	Demonstration of gratitude for support during the difficult COVID-19 era.
Community Building	Reaching out to individuals of common interests.
Anecdote	User shares anecdotal lived experience(s) of a certain circumstance/challenge.
Advertisement	An ad or coupon code promoting traffic to a service or product.
General Curiosity	User demonstrates a general curiosity for the topic and/or its contextual relevance.
App Promotion and User Engagement	A set of strategies, activities, and techniques used by app developers and marketers to increase the visibility and usage of a mobile application (app) among its target audience. This involves promoting the app to attract new users and engaging existing users to ensure they continue using the app regularly.
Investment and Financial Analysis	Refers to the process of evaluating the financial performance, viability, and potential risks and rewards associated with investments. It involves using various financial metrics, techniques, and models to assess the attractiveness of an investment opportunity, make informed investment decisions, and manage financial assets effectively.

We note that 83.5% of the data had the same codes.

By analyzing the frequency of the posts that were categorized under each topic in Table 14, we noticed that 6% of the data belonged to the “Community Building”, 4.7% to the “Community Appreciation”, and only 5.8% of the posts were coded into “Anecdote”, “Advertisement”, “General Curiosity”, “App Promotion and User Engagement”, and “Investment and Financial Analysis” topics. However, it is important to note that 83.5% of the posts were labeled with the codes in Table 3. This observation demonstrated that while some of the challenges of IT workers might evolve or new ones might arise over time, their main concerns around “Skill Development”, “Job Applications/Job Search”, “Education”, and “Employment/Job Concerns” remained the same over time.

C Performance Comparison of Machine Learning Classifiers

In this section, we provide a performance comparison of the five trained machine learning models for the topic classification task. This comparison can be found in Table 15.

Table 15. Comparison of the Performances of the 5 Trained Machine Learning Models for the Topic Classification Task

Topic	Classifier	Precision	Recall	F1-Score
Job Applications/Job Search	BERT (base uncased)	0.76	0.77	0.76
	XLNet	0.77	0.78	0.77
	LR	0.75	0.68	0.72
	LinearSVC	0.74	0.68	0.71
	RF	0.77	0.18	0.29
Skill Development	BERT (base uncased)	0.82	0.84	0.83
	XLNet	0.84	0.85	0.85
	LR	0.81	0.81	0.81
	LinearSVC	0.83	0.78	0.80
	RF	0.57	0.85	0.68
Employment/Job Concerns	BERT (base uncased)	0.73	0.74	0.73
	XLNet	0.73	0.83	0.78
	LR	0.66	0.73	0.70
	LinearSVC	0.64	0.71	0.67
	RF	0.71	0.06	0.12
Education	BERT (base uncased)	0.77	0.78	0.77
	XLNet	0.79	0.79	0.79
	LR	0.73	0.75	0.74
	LinearSVC	0.70	0.75	0.73
	RF	0.82	0.13	0.23
Other	BERT (base uncased)	0.90	0.87	0.88
	XLNet	0.91	0.87	0.89
	LR	0.87	0.86	0.87
	LinearSVC	0.84	0.88	0.86
	RF	0.77	0.88	0.82
Mean	BERT (base uncased)	0.834	0.832	0.833
	XLNet	0.848	0.845	0.846
	LR	0.807	0.806	0.806
	LinearSVC	0.801	0.797	0.797
	RF	0.698	0.667	0.602

The overall accuracy for all the topics is reported at the end of the table. The outperforming model based on F1-score is XLNet.

Received 23 July 2025; revised 9 March 2026; accepted 9 April 2026
